

# Python Basics

# Basics of Python for Data Analysis

- ▶ **Open Source – free to install**
- ▶ **Very easy to learn**
- ▶ **Can become a common language for data science and production of web based analytics products.**
- ▶ **It is an interpreted language and compiled language**

# Python Properties

1. *Strongly* typed. It enforces data types so you can't concatenate a string and a integer, for example.

2. *Dynamically, implicitly* typed. So, you don't have to explicitly declare variable data types. Data types are enforced at runtime.

3. *Case sensitive*. For example, token and TOKEN are two different variables.

4. *Object-oriented*.

# Python inventor

- ▶ **Guido Van Rossum** inventor of Python
- ▶ **General Purpose** programming language
- ▶ **Build anything**
- ▶ **Can build packages for data science**

# Python Framework

- ▶ **Anaconda Framework**

- ▶ Jupyter Notebook

- ▶ Python 3.x

- Operating system version**

- ▶ *Mac:*

- ▶ *Linux:*

- ▶ *Windows:*

# Python script

- ▶ Python Files `-.ipynb`
- ▶ List of Python commands
- ▶ Executing the script

# Python basic syntax

- ▶ `>>> 3+4`
- ▶ `7`
- ▶ `>>> 4*4`
- ▶ `16`
- ▶ `>>> 5-2`
- ▶ `3`
- ▶ `>>> 8/2`
- ▶ `4.0`
- ▶ `>>> a=9`
- ▶ `>>> b=2`
- ▶ `>>> c=a+b`
- ▶ `>>> print(c)`
- ▶ `11`

# python calculator

- ▶ `>>> print(8+2)`
- ▶ `print(5 + 5)`
- ▶ `print(5 - 5)`
- ▶ `# Multiplication, division, modulo, and exponentiation`
- ▶ `print(3 * 5)`
- ▶ `print(10 / 2)`
- ▶ `print(18 % 7)`
- ▶ `print(4 ** 2)`

# Print -String

- ▶ `>>> print ('hello world')`
- ▶ `hello world`
  
- ▶ `Print("hello world")`
- ▶ `Hello world`

# Variables

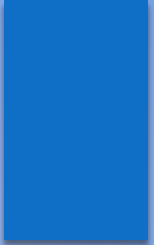

- ▶ Variables are containers for data.
- ▶ The syntax to declare them is:
  - ▶ `variable_name = variable_value.`
  - ▶ `X=25`
  - ▶ `Y=69`
  - ▶ `Z=80`

# Variables example...

- ▶ `number1 = 50`
- ▶ `number2=100`
- ▶ `Result=number1 +number2`
  
- ▶ `First=45`
- ▶ `Second=5`
- ▶ `Third=First+Second`

# Variables

- ▶ `>>> var1=89`
- ▶ `>>> print(var1)`
- ▶ `89`
- ▶ `>>> var2='Hello'`
- ▶ `>>> print(var2)`
- ▶ `Hello`
- ▶ `>>> addvar=8+5`
- ▶ `>>> print(addvar)`
- ▶ `13`

- 
- ▶ `>>> multiplyvar=8*5`
  - ▶ `>>> print('Multiply='+multiplyvar)`
  - ▶ Traceback (most recent call last):
  - ▶ File "<stdin>", line 1, in <module>
  - ▶ TypeError: must be str, not int
  - ▶ `>>> print('Multiply='+ str(multiplyvar))`
  - ▶ `Multiply=40`
  - ▶ `>>>`

# Built-in Data Types

- ▶ Python has a number of built-in data types such as numbers (integers, floats, complex numbers), strings, lists, tuples, and dictionaries.
- ▶ Each of these can be manipulated using:
  - ▶ Operators
  - ▶ Functions

# Numbers

Numbers can be integers, floating points, Booleans, or complex numbers. The former three are the most important:

- Integers are whole numbers - 1, 2, 22, 476, -99999
- Floats have decimal points - 1.0, 2.22, 22.098, 476.1, -99999.9
- Booleans represent either True or False (or 1 or 0). They represent data that can only be one thing or another.

# Operators

```
>>> 2 + 3 # Addition  
5
```

```
>>> num1 = 10
```

```
>>> num2 = 9.99
```

```
>>> num3 = num1 + num2
```

```
>>> num3  
19.990000000000002
```

# Operators

▶ `>>> 8 - 5 # Subtraction`

▶ `3`

▶ `>>> 2 * 6 # Multiplication`

▶ `12`

▶ `>>> 12 / 3 # Division`

▶ `4.0`

▶ `>>> 7 % 3 # Modulus (returns the remainder from division)`

▶ `1`

▶ `>>> 3 ** 2 # Raise to the power 9`

# operators

- ▶ `>>> savings=100`
- ▶ `>>> factor=1.10`
- ▶ `>>> result=savings*factor**6`
- ▶ `>>> print(result)`
- ▶ `177.15610000000001`

# Operators..

- ▶ `>>> 2 < 5`
- ▶ `True`
- ▶ `>>> 4 > 10`
- ▶ `False`
- ▶ `>>> 3 >= 3`
- ▶ `True >>>`
- ▶ `>>> 5 == 6`
- ▶ `False >>>`
- ▶ `6 != 9` True

# Variable ---specific

- ▶ Calculating Body Mass Index-BMI
  - ▶ height=1.79
  - ▶ weight=68.7
  - ▶ bmi=weight/height\*\*2
  - ▶ print(bmi)

# Functions

- ▶ Python provides you with a number of built-in functions for manipulating integers. These are *a*lways available to you
- ▶ `>>> float(9)`
- ▶ `9.0`
- ▶ `>>>int(5.7)`
- ▶ `5`
- ▶ `>>>int(3.45)`
- ▶ `3`

# Strings

- ▶ `>>> simple_string = "hey!"`
- ▶ `>>> simple_string`
- ▶ `'hey!'`
- ▶ `>>> "hello world!"`
- ▶ `'hello world!'`
- ▶ `>>> escaped = 'can\'t'`
- ▶ `>>> escaped`
- ▶ `"can't"`

# Manipulating strings

- ▶ *Operators*
- ▶ Like numbers, you can concatenate strings (string concatenation):
- ▶ `>>> "happy"+" " +"birthday"`
- ▶ `'happy birthday'`
- ▶ `>>> "Jonas" + "Brother"`
- ▶ `JonasBrother`

# Functions

- ▶ `len()` - given a string, this function returns the length of it.
- ▶ `>>> city = "London"`
- ▶ `>>> len(city)`

# Slice()

- ▶ slice() - given a start and stop value, you can access a set of, or single, character(s)

```
>>> ("Hello"[2])
```

```
|
```

```
>>> ("Hello"[3])
```

```
|
```

```
>>> ("Hello"[0])
```

```
H
```

```
>>> ("Hello"[0:2])
```

```
He
```

# String.format()

- ▶ Easily format values into strings

```
>>> name=" Maria Joe"
```

```
>>>greeting ="My name is {}".format(name)
```

```
>>> greeting
```

# Guess the type-- gives the data type

- ▶ `>>> a=10`
- ▶ `>>> type(a)`
- ▶ `<class 'int'>`
- ▶ `>>> str="hello"`
- ▶ `>>> type(str)`
- ▶ `<class 'str'>`
- ▶ `>>> d=4.45`
- ▶ `>>> type(d)`
- ▶ `<class 'float'>`
- ▶ `>>>`

# script1.ipynb-----Python Script

- ▶ height=1.79
- ▶ weight=68.7
- ▶ bmi=weight/height\*\*2
- ▶ print(bmi)

# Python types

- ▶ `>>>type(bmi)`
- ▶ `float`
- ▶ `day=5`
- ▶ `type(day)`

# LOOPS

- ▶ `>>> print ('loop')`
- ▶ `loop`
- ▶ `>>>`
- ▶ `>>> ctr=1`
- ▶ `>>> while condition < 10:`
- ▶ `... print(condition)`
- ▶ `File "<stdin>", line 2`
- ▶ `print(condition)`
- ▶ `^`
- ▶ `IndentationError: expected an indented block`
